

Function: `addStyleSheet(sheetName)`

It changes the style sheet that the web page is using. Parameter `sheetName` is the name of the style sheet to be used.

This function works by first attempting to find an element with the ID `'cssFile'` within the given HTML document. If this function finds such an element, it changes its `href` attribute to the value given by the parameter `sheetName`. It effectively changes the current stylesheet for a new one by updating the `href` attribute. This allows the visual of the webpage to change in real time without refreshing or reloading it.

When clicking the buttons (using the `onclick` event), the function is called with a string value as an argument. There are three styles available, each with its own button: Style A, Style B, and Style C.

For example, if you click the Style A button, it changes the `href` attribute of the element to `'styleA.css'`.
